FOOT-AND-MOUTH DISEASE IN BEEF CATTLE

Foot-and-mouth disease (FMD) is one of the most contagious animal diseases and is caused by FMD virus. Although FMD occurs in many parts of the world, Australia is recognised as free from FMD without vaccination.

SIGNS

FMD affects domestic and wild cloven-hoofed animals including cattle, pigs, sheep, goats, deer and water buffalo. Horses are not susceptible. The virus is not a threat to human health.

In **beef cattle**, the clinical signs of FMD are:

- · Dullness*
- Poor appetite*
- High fever (40-41°C)*
- · Excessive drooling and lip smacking
- Nasal discharge
- · Lameness, depending on the stage of infection
- · Separation from the mob
- · Unwilling or unable to stand
- Lethargy
- · Rapid loss of condition
- Blisters or erosions inside the mouth (tongue, cheeks, gums, lips and/or palate) or skin between the claws at the coronary band
- Abortion
- Sudden death in youngstock

HOW IS FMD TRANSMITTED?

FMD virus can be shed in the fluid of ruptured blisters, exhaled air, saliva, milk, semen, faeces and urine. Animals are infected by inhalation, ingestion and artificial or natural breeding. The incubation period is 14 days and infected animals can spread the virus before showing any clinical signs of disease. In cattle, direct contact and inhalation of contaminated aerosols is the primary route of transmission. Movement of infected animals is one of the most important routes by which FMD spreads between herds and farms. Transmission easily occurs when animals are in close proximity at watering and feeding points and during congregation in stockyards. Contaminated clothing, equipment and vehicles can also spread the disease. The FMD virus can remain infective in the environment for several weeks to months in soil, manure, dried animal secretions, straw, hair and leather.
